

Linear Regression Part 2

Date: 25th May 2026

Topics

- ❖ Degrees of Freedom
- ❖ Residual Variance
- ❖ Resolution of Sum of Squares
- ❖ Finding R^2 and Adjusted R^2
- ❖ Variance-Covariance Matrix

Actual response and its prediction

Express the deviation between an actual response (Y_i) and the predicted response ($\hat{Y}_i$) in terms of difference of two deviations

- ❖ Deviation of actual response from mean response $\bar{Y}$:

$$Y_i - \bar{Y}$$

- ❖ Deviation of predicted response from mean response:

$$\hat{Y}_i - \bar{Y}$$

How to Find Mean Response?

$$\bar{Y} = \frac{\sum_{i=1}^n Y_i}{n}$$

Interesting Aside: It may be shown that the mean of the predicted responses is the same as the mean of the actual (experimental) responses

$$\bar{Y} = \frac{\sum_{i=1}^n \hat{Y}_i}{n} = \bar{\hat{Y}}$$

Relation between actual response and its prediction

- ❖ Deviation of actual response from mean response
- ❖ Deviation of predicted response from mean response

$$(Y_i - \bar{Y}) = (Y_i - \hat{Y}_i) + (\hat{Y}_i - \bar{Y})$$

or

$$(Y_i - \hat{Y}_i) = (Y_i - \bar{Y}) - (\hat{Y}_i - \bar{Y})$$

$$(Y_i - \bar{Y}) = (Y_i - \hat{Y}_i) + (\hat{Y}_i - \bar{Y})$$

or

$$(Y_i - \hat{Y}_i) = (Y_i - \bar{Y}) - (\hat{Y}_i - \bar{Y})$$

Sum of Squares

It may be shown that

$$\sum_{i=1}^n (Y_i - \bar{Y})^2 = \sum_{i=1}^n (Y_i - \hat{Y}_i)^2 + \sum_{i=1}^n (\hat{Y}_i - \bar{Y})^2$$

This amounts to

Sum of Squares of the Deviations of the Responses from the Mean =

Sum of Squares of the Residuals + Sum of Squares due to Regression

Degrees of Freedom (DOF)

Broadly, let there be a group of numerical entities $X_1, X_2, \dots, X_n$.

Suppose we use these to find the mean value.

$$\bar{X} = \frac{\sum_{i=1}^n X_i}{n}$$

Now, one relation, viz. mean(or average) has been found from these n numbers.

Sum of Deviations from the Mean

Let us define deviation from mean (d_i) as

$$d_i = X_i - \bar{X}$$

What is $\sum_{i=1}^n d_i$?

Sum of Deviations from the Mean

Let us define deviation from mean (d_i) as

$$d_i = X_i - \bar{X}$$

$$\sum_{i=1}^n d_i = \sum_{i=1}^n X_i - \sum_{i=1}^n \bar{X}$$

$$\bar{X} = \frac{\sum_{i=1}^n X_i}{n}$$

$$\sum_{i=1}^n d_i = n\bar{X} - n\bar{X} = 0$$

Hence, sum of deviations equals zero.

Sum of Deviations from the Mean

Hence, sum of deviations equals zero

$$\sum_{i=1}^n d_i = 0$$

$$d_1 + d_2 + \dots + d_i + \dots + d_n = 0$$

Here there are only $n-1$ independent deviations as the i^{th} deviation d_i may be found as follows

$$d_i = -(d_1 + d_2 + d_{i-1} + d_{i+1} + \dots + d_n)$$

Sample Standard Deviation S^2

Hence, the standard deviation of the sample is defined as

$$S^2 = \frac{\sum_{i=1}^n d_i^2}{n-1} = \frac{\sum_{i=1}^n (X_i - \bar{X})^2}{n-1}$$

S^2 is based upon using the sample mean in its definition which in turn is based on only $n-1$ independent deviations from the sample mean.

Sample Standard Deviation S^2

$$S^2 = \frac{\sum_{i=1}^n d_i^2}{n-1} = \frac{\sum_{i=1}^n (X_i - \bar{X})^2}{n-1}$$

- ❖ The sum of squares of the deviations from the mean $\sum_{i=1}^n d_i^2$ involves only $n-1$ independent squared deviations.
- ❖ Hence, there are only $n-1$ degrees of freedom among the n d_i^2 due to the constraint $\sum_{i=1}^n d_i = 0$

Degrees of Freedom

$$SS_{\text{Total}} = SS_{\text{Regression}} + SS_{\text{Residual}}$$

$$\sum_{i=1}^n (Y_i - \bar{Y})^2 = \sum_{i=1}^n (Y_i - \hat{Y}_i)^2 + \sum_{i=1}^n (\hat{Y}_i - \bar{Y})^2$$

DOF: $n-1$ $n-p$ + $k (=p-1)$

The SS_{Total} has $n-1$ degrees of freedom (HOW?)

The $SS_{\text{Regression}}$ has k degrees of freedom where k is related to total number of regression coefficients as

Omitting β_0

- ❖ Hence, it may be seen that the parameter β_0 has been omitted from the regression sum of square and
- ❖ Only the partial regression coefficients $\beta_1, \beta_2, \dots, \beta_k$ have been included

Why n-p in SS_{Residual} ?

$$\frac{\sum_{i=1}^n e_i^2}{n-p} = \frac{SS_{\text{Residual}}}{n-p} \qquad SS_{\text{Residual}} = \sum_{i=1}^n (Y_i - \hat{Y}_i)^2$$

$$SS_{\text{Residual}} = \sum_{i=1}^n (Y_i - \hat{\beta}_0 - \hat{\beta}_1 X_i)^2$$

- ❖ Two parameters $\hat{\beta}_0$ and $\hat{\beta}_1$ are estimated here from the data.
- ❖ Two constraints operate on the sum of squares.
- ❖ The constraints operating on $\sum_{i=1}^n (Y_i - \hat{\beta}_0 - \hat{\beta}_1 X_i)^2$ are

$$\frac{\partial SS_E}{\partial \hat{\beta}_0} = \frac{\partial}{\partial \hat{\beta}_0} \left[\sum_{i=1}^n (Y_i - \hat{\beta}_0 - \hat{\beta}_1 X_i)^2 \right] = 0 \qquad \frac{\partial SS_E}{\partial \hat{\beta}_1} = \frac{\partial}{\partial \hat{\beta}_1} \left[\sum_{i=1}^n (Y_i - \hat{\beta}_0 - \hat{\beta}_1 X_i)^2 \right] = 0$$

Why n-p?

- ❖ Two parameters are estimated here from the data. Two constraints operate on the sum of squares.
- ❖ The constraints operating on $\sum_{i=1}^n (Y_i - \hat{\beta}_0 - \hat{\beta}_1 X_i)^2$ are

$$\frac{\partial SS_E}{\partial \hat{\beta}_0} = \frac{\partial}{\partial \hat{\beta}_0} \left[\sum_{i=1}^n (Y_i - \hat{\beta}_0 - \hat{\beta}_1 X_i)^2 \right] = 0$$

$$\frac{\partial SS_E}{\partial \hat{\beta}_1} = \frac{\partial}{\partial \hat{\beta}_1} \left[\sum_{i=1}^n (Y_i - \hat{\beta}_0 - \hat{\beta}_1 X_i)^2 \right] = 0$$

Analysis of Variance (ANOVA)

Source of Variation	Sum of Squares	Degrees of Freedom
Regression	$SS_{\text{Regression}}$	$k = p - 1$
Residual	SS_{Residual}	$n - p$
Total	SS_{Total}	$n - 1$

Source of Variation	Sum of Squares	Degrees of Freedom
Regression	$SS_{\text{Regression}}$	k
Residual	SS_{Residual}	n-p
Total	SS_{Total}	n-1

Here n is the total number of observations and p is the total number of parameters (including the constant β_0).

$$\text{Since } k = (n-1) - (n-p)$$

$$\mathbf{k = p-1}$$

Definition of Total Sum of Squares

The total sum of squares is defined as

$$SS_{\text{total}} = \sum_{i=1}^n (Y_i - \bar{Y})^2$$

Derivation of Total Sum of Squares

$$\begin{aligned}SS_{\text{total}} &= \sum_{i=1}^n (Y_i - \bar{Y})^2 = \sum_{i=1}^n Y_i^2 - \frac{(\sum_{i=1}^n Y_i)^2}{n} \\&= \mathbf{Y}'\mathbf{Y} - \frac{(\sum_{i=1}^n Y_i)^2}{n}\end{aligned}$$

$$SS_{\text{Total}} = \mathbf{Y}'\mathbf{Y} - n\bar{Y}^2$$

Derivation for Actual Regression Sum of Squares

$$SS_{\text{Residual}} = \mathbf{e}'\mathbf{e}$$

$$= (\mathbf{Y} - \mathbf{X}\hat{\boldsymbol{\beta}})'(\mathbf{Y} - \mathbf{X}\hat{\boldsymbol{\beta}})$$

$$= (\mathbf{Y}'\mathbf{Y} - 2\hat{\boldsymbol{\beta}}' \mathbf{X}'\mathbf{Y} + \hat{\boldsymbol{\beta}}\mathbf{X}'\mathbf{X} \hat{\boldsymbol{\beta}})$$

$$= (\mathbf{Y}'\mathbf{Y} - 2\hat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{Y} + \hat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{Y})$$

$$SS_{\text{Residual}} = (\mathbf{Y}'\mathbf{Y} - \hat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{Y}) \text{ As } \mathbf{X}'\mathbf{X} \hat{\boldsymbol{\beta}} = \mathbf{X}'\mathbf{Y}$$

$$SS_{\text{Residual}} = \text{Actual } SS_{\text{Total}} + \text{Actual } SS_{\text{Regression}}$$

Manipulation of Residual Sum of Squares

$$SS_{\text{Residual}} = SS_{\text{total}} - SS_{\text{regression}}$$

We previously defined SS_{Residual} as follows

$$SS_{\text{Residual}} = (\mathbf{Y}'\mathbf{Y} - \hat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{Y})$$

$$SS_{\text{Residual}} = \mathbf{Y}'\mathbf{Y} - SS_{\text{Regression}}$$

Subtracting $n\bar{Y}^2$ from both terms on RHS we get

$$SS_{\text{Residual}} = (\mathbf{Y}'\mathbf{Y} - n\bar{Y}^2) - (\hat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{Y} - n\bar{Y}^2)$$

Resolution of Error Sum of Squares

$$SS_{\text{Residual}} = (Y'Y - \hat{\beta}'X'Y)$$

$$SS_{\text{Residual}} = \left(Y'Y - \frac{(\sum_{i=1}^n Y_i)^2}{n} \right) - \left(\hat{\beta}'X'Y - \frac{(\sum_{i=1}^n Y_i)^2}{n} \right)$$

$$SS_{\text{Residual}} = SS_{\text{total}} - SS_{\text{regression}}$$

By definition of the total sum of squares, the second term becomes the regression sum of squares

Manipulation of Residual Sum of Squares

$$SS_{\text{Residual}} = (\mathbf{Y}'\mathbf{Y} - n\bar{Y}^2) - (\hat{\boldsymbol{\beta}}'\mathbf{X}'\mathbf{Y} - n\bar{Y}^2)$$

$$SS_{\text{Residual}} =$$

$$(\text{Actual } SS_{\text{Total}} \text{ corrected for } \beta_0) - (SS_{\text{Regression}} \text{ corrected for } \beta_0)$$

Hence sum of squares due to β_0 is given by $n\bar{Y}^2$

Total Sum of Squares

Total Sum of Squares: $\mathbf{Y}'\mathbf{Y} - \frac{(\sum_{i=1}^n Y_i)^2}{n}$

The *actual* total sum of squares is $\mathbf{Y}'\mathbf{Y}$.

The term $n\bar{Y}^2 = \frac{(\sum_{i=1}^n Y_i)^2}{n}$ is deducted from the *actual* total sum of squares.

Regression Sum of Squares due to Partial Regression Coefficients

- ❖ The regression sum of squares does NOT include the intercept β_0 contribution and
- ❖ Has contributions only from $\beta_1, \beta_2, \beta_3, \dots \beta_k$.
- ❖ Hence the degrees of freedom for this regression sum of squares is $k (= p-1)$.

Regression Sum of Squares due to β_0

Another way of looking at this is as follows

If we fit a model containing only β_0 , the fitted model is

$$\hat{Y} = \bar{Y}$$

or

$$\beta_0 = \bar{Y}$$

There is no contribution from the predictors

Regression Sum of Squares due to β_0

$$\beta_0 = \bar{Y}$$

There is no contribution from the predictors

Hence sum of squares due to β_0 is

$$\sum_{i=1}^n \bar{Y}^2 = n\bar{Y}^2$$

Metrics of Regression :

How Good is my Fit?

Coefficient of Determination (R^2):

$$R^2 = \frac{SS_{\text{Regression}}}{SS_{\text{Total}}}$$

This represents the proportion of the total variability accounted or explained by the linear regression model

Coefficient of Determination (R^2):

The R^2 value may be increased by increasing the number of terms in the model and thereby increasing the number of coefficients that may be adjusted so that the model can be made to fit the data excellently.

Coefficient of Determination (R^2):

- ❖ A complex model becomes cumbersome to handle, more empirical in nature and difficult to ascribe physical reasons for the dependence of the response on the factors of the experiment.
- ❖ A noisy data fitted with too many parameters will fail to work well when implemented.

Adjusted R²:

Here Mean Squares of the error and model/total sum of squares are used.

$$R^2 = 1 - \frac{SS_{\text{Residual}}}{SS_{\text{Total}}}$$

$$\text{Adj. } R^2 = 1 - \frac{\left\{ \frac{SS_{\text{Residual}}}{n-p} \right\}}{\left\{ \frac{SS_{\text{Total}}}{(n-1)} \right\}}$$

Hi or lo?

$SS_{\text{Residual}} \downarrow$
 $\frac{1}{n-p} \uparrow$
 $p \uparrow$

Adjusted R²:

$$R^2_{\text{adj}} = 1 - \frac{\text{SS}_{\text{Error}} / n - p}{\text{SS}_{\text{Total}} / n - 1}$$

Handwritten notes:

- SS_{Error} is labeled *Residual* in red.
- $n - p$ is labeled *dof of SS_{Residual}* in red.
- $n - 1$ is circled in red and labeled *dof SS_{Total}* in red.

To penalize the addition of unnecessary terms in the model equation (“overfitting”) the adjusted R² value also gets reported.

Adjusted R²:

$$R^2_{\text{adj}} = 1 - \frac{\text{SS}_{\text{Error}} / n - p}{\text{SS}_{\text{Total}} / n - 1}$$

Residual

The SS_{Error} contribution is increased by dividing with the error degrees of freedom. The latter reduces when more number of parameters are taken up by the model.

Adjusted R²:

$$R_{\text{adj}}^2 = 1 - \frac{\text{SS}_{\text{Error}} / n - p}{\text{SS}_{\text{Total}} / n - 1}$$

Unless the SS_{Error} is considerably reduced by adding the extra term to the model equation, the adjusted R^2 will increase upon increasing the number of parameters.

PRESS: Prediction Error Sum of Squares

- ❖ This term is also similar to the sum of squares of the residuals.

0.95 1. R^2
0.88 2. Adj. R^2
3. PRESS R^2
0.74

- ❖ We sum the square of the deviations between the actual responses and the corresponding model predicted values.

PRESS: Prediction Error Sum of Squares

The main difference to watch out for is that the prediction for the i^{th} data is based on a model equation that *excluded* that particular data point but used the remaining data points to develop the model equation.

1000 data points
H Matrix

$$\begin{array}{ccc} x & y & x_1, x_2, \dots, x_{i-1}, x_{i+1}, \dots, x_n \\ x_1 & y_1, \hat{y}_1 & y_1, y_2, \dots, y_{i-1}, y_{i+1}, \dots, y_n \\ x_2 & y_2, \hat{y}_2 & \\ \vdots & \vdots & \\ x_i & y_i, \hat{y}_i & \\ \vdots & \vdots & \\ x_n & y_n & \end{array}$$

$\hat{y}_{\text{pred}} \rightarrow \hat{y}_{\text{pred w/o } i} = \hat{\beta}_0 + \hat{\beta}_1 x_i$

PRESS: Prediction Error Sum of Squares

- ❖ The same treatment is meted to other data points as well when they are compared to their individual model predictions.

PRESS:

First **H** matrix is defined as follows

$$\mathbf{H} = \mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'$$

idempotent matrix

Let us define the usual residual

$$e_i = (y_i - \hat{y}_i)$$

The PRESS residual $e_{(i)}$ may be related to e_i as

$$\underline{e_{(i)}} = e_i / (1 - h_{ii})$$

$$\begin{bmatrix} h_{11} & & \\ & h_{22} & \text{non zero} \\ & & \ddots \\ & & & h_{nn} \end{bmatrix}$$

Here, h_{ii} refers to the diagonal elements of **H**.

$$\begin{bmatrix} 1 & 3 & 4 \\ & & \end{bmatrix}$$

PRESS:

The PRESS residual $e_{(i)}$ may be related to e_i as

$$e_{(i)} = \frac{e_i}{1 - h_{ii}}$$

Here, h_{ii} refers to the diagonal elements of **H**

$$\text{PRESS} = \sum_{i=1}^n \left(\frac{e_i}{1 - h_{ii}} \right)^2$$

$$R_{\text{PRESS}}^2 = 1 - \frac{\text{PRESS}}{\text{SS}_{\text{Total}}} \rightarrow Y'Y - n\bar{Y}^2$$

Remember to adjust for intercept when finding total sum of squares

Variance-Covariance Matrix

The variance-covariances of the least square estimators of the parameters $\hat{\beta}$ including $\hat{\beta}_0$ are the elements of the $(\mathbf{X}'\mathbf{X})^{-1}$ matrix multiplied by the variance σ^2 .

$(\mathbf{X}'\mathbf{X})^{-1} \sigma^2$ is termed as the
Variance-Covariance matrix.

$\hat{\beta}_0, \hat{\beta}_1, \hat{\beta}_2$ more precise

$\hat{\beta}_0$
 $\hat{\beta}_1$ large variance
model prediction
imprecise

Variance-Covariance Matrix

The diagonal elements of the Covariance matrix are the **variances of the least square estimators** and the off-diagonal elements are the **covariances**.

Hand-drawn diagram illustrating the structure of the Covariance matrix. The matrix is shown as a square box containing elements C_{00} , C_{11} , and C_{RR} on the diagonal, and question marks for off-diagonal elements. The parameters being estimated are $\hat{\beta}_0$, $\hat{\beta}_1$, and $\hat{\beta}_k$. The matrix is scaled by σ^2 . An arrow points from the C_{RR} element to the $\hat{\beta}_k$ label.

The Covariance matrix dimensions are $p \times p$

$$V(\hat{\beta}_0) = C_{00} \sigma^2$$
$$V(\hat{\beta}_k) = C_{kk} \sigma^2$$

Form of the Variance-Covariance Matrix

$$\mathbf{C} = (\mathbf{X}'\mathbf{X})^{-1} \sigma^2 = \begin{bmatrix} C_{00} & C_{01} & C_{02} \\ C_{10} & C_{11} & C_{12} \\ C_{20} & C_{21} & C_{22} \end{bmatrix} \sigma^2$$

$\text{Cov}(\hat{\beta}_0, \hat{\beta}_1) = C_{01}$
 $C_{10} = \text{Cov}(\hat{\beta}_1, \hat{\beta}_0)$
 $C_{01} = C_{10}$
 Symmetric

σ^2
 $\begin{bmatrix} 1 & 4 & 5 \\ 2 & 6 & 3 \end{bmatrix}$
 $\cdot$
 $(\mathbf{X}'\mathbf{X})^{-1} \sigma^2$
 $\hat{\beta}$

Matrix Form of the Regression Equations

This is a symmetric matrix

($C_{10}=C_{01}$, $C_{20}=C_{02}$, and $C_{21}=C_{12}$) as $(\mathbf{X}'\mathbf{X})^{-1}$ is symmetric.

$$V(\hat{\beta}) = \sigma^2 C_{jj}, j = 0, 1, 2$$

$$\text{Cov}(\hat{\beta}_i, \hat{\beta}_j) = \sigma^2 C_{ij}, i, j = 0, 1, 2, i \neq j$$

Significance of the Covariance Matrix

The estimates of the variances of these estimated regression coefficients are obtained by replacing σ^2 with an estimate $\hat{\sigma}^2$ as σ^2 is unknown.

What is a suitable Surrogate for σ^2

$$Y = X\beta + \varepsilon$$

Residual

$$Y - X\beta = \varepsilon$$

$$\hat{Y} - X\hat{\beta} = ?$$

$$\begin{array}{cc} \beta_1 & \hat{\beta}_1 \\ \sigma^2 \rightarrow & \hat{\sigma}^2 \\ \text{Error} & \text{Variance} \end{array}$$

Estimated Standard Error

When σ^2 is replaced by its estimate $\hat{\sigma}^2$, the square root of the estimated variance of the j^{th} regression coefficient is called the **estimated standard error** of the least squares estimator $\hat{\beta}_j$

Significance of the Covariance Matrix

The estimated standard error of the least squares estimator is given by

$$se(\hat{\beta}_j) = \sqrt{\hat{\sigma}^2 C_{jj}}$$

Significance of the Covariance Matrix

- ❖ These standard errors are a measure of the precision of the estimation for the regression coefficients
- ❖ Small standard errors imply good precision.

Estimator of Standard Error

- ❖ The estimation of residual error is important
- ❖ The residual should ideally reflect the difference due to random factors and not systematic discrepancies created by using an inadequate model.
- ❖ This is an unbiased estimator of σ^2

Estimator of Residual Variance

$$\hat{\sigma}^2 = \frac{\sum_{i=1}^n e_i^2}{n - p} = \frac{SS_{\cancel{E} \text{Residual}}}{n - p}$$

$$SS_{\cancel{E} \text{Residual}} = \sum_{i=1}^n (Y_i - \hat{Y}_i)^2$$

Standard Error

$$se(\hat{\beta}_j) = \sqrt{\hat{\sigma}^2 C_{jj}}$$

Handwritten red annotations showing the calculation of standard errors for β_0 and β_1 :

- For β_0 : $\hat{\beta}_0 = 10$, $SE(\hat{\beta}_0) = 0.2$
- For β_1 : $\hat{\beta}_1 = 1$, $SE(\hat{\beta}_1) = 0.1$
- For β_2 : $\hat{\beta}_2 = 0.5$, $SE(\hat{\beta}_2) = 0.5$

Compare the standard errors $se(\hat{\beta}_j)$ with the estimated coefficients $\hat{\beta}_j$ and if the standard errors are much smaller than these coefficients, **the precision** of estimation is reasonably good.

Tutorial Problem

For the conveyor belt problem find

- e) Standard Error of the Estimated Parameters

a) Coefficient of Determination R^2

Previously the total sum of squares and regression sum of squares were actual values viz.

$$\text{Actual } SS_{\text{Total}} = \sum_{i=1}^n Y_i^2 \quad \& \quad \text{Actual } SS_{\text{Regression}} = \beta'X'Y$$

But we need to use

$$SS_{\text{Total}} = \sum_{i=1}^n Y_i^2 - n\bar{Y}^2 \quad \& \quad SS_{\text{Regression}} = \sum_{i=1}^n \beta'X'Y - n\bar{Y}^2$$

If you may recall, we are removing the effect of the intercept β_0 and focussing on the partial regression coefficients.

a) Coefficient of Determination (R^2):

$$R^2 = \frac{SS_{\text{Regression}}}{SS_{\text{Total}}}$$

From Matlab we get the following results for the II order model

$$R^2 = \frac{SS_{\text{Regression}}}{SS_{\text{Total}}}$$

a) Coefficient of Determination R^2

Previously the total sum of squares and regression sum of squares were actual values viz.

$$\text{Actual } SS_{\text{Total}} = \sum_{i=1}^n Y_i^2 \quad \& \quad \text{Actual } SS_{\text{Regression}} = \beta'X'Y$$

But we need to use

$$SS_{\text{Total}} = \sum_{i=1}^n Y_i^2 - n\bar{Y}^2 \quad \& \quad SS_{\text{Regression}} = \sum_{i=1}^n \beta'X'Y - n\bar{Y}^2$$

If you may recall, we are removing the effect of the intercept β_0 and focussing on the partial regression coefficients.

% For II order model find Total and Regression Sum of Squares

$SS_Total = Y' * Y - \text{numel}(Y) * \text{mean}(Y)^2;$ % 228.9091

$SS_Regression = \text{beta_hat}' * X' * Y - \text{numel}(Y) * \text{mean}(Y)^2;$ % 221.6775

% $\text{numel}(Y) = 11$ value of n

$n = \text{numel}(Y);$ % n=11

$R2_IorderModel = SS_Regression / SS_Total;$ % $R^2 = 0.9684$

a) Coefficient of Determination (R^2):

$$R^2 = \frac{SS_{\text{Regression}}}{SS_{\text{Total}}}$$

From Matlab we get the following results for the II order model

$$R^2 = \frac{221.6775}{228.9091} = 0.9684$$

b) Adjusted R²

% Next to find Adjusted R²

p = numel(beta_hat) % 3

R2Adj_IlderModel = 1 - (RsSSQ1/(n-p))/(SS_Total/(n-1));

% R2_Adj = 0.9605

$$\text{Adj. } R^2 = 1 - \frac{\frac{SS_{\text{Residual}}}{n - p}}{\frac{SS_{\text{Total}}}{n - 1}}$$

$$\text{Adj. } R^2 = 1 - \frac{\frac{7.2316}{11-3}}{\frac{228.9091}{11-1}} = 0.9605$$

c) PRESS

First **H** matrix is defined as follows

$$\mathbf{H} = \mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'$$

Let us define the usual residual

$$e_i = (y_i - \hat{y}_i)$$

The PRESS residual $e_{(i)}$ may be related to e_i as

$$e_{(i)} = e_i / (1 - h_{ii})$$

Here, h_{ii} refers to the diagonal elements of **H**.

c) PRESS:

The PRESS residual $e_{(i)}$ may be related to e_i as

$$e_{(i)} = \frac{e_i}{1 - h_{ii}}$$

Here, h_{ii} refers to the diagonal elements of **H**

$$\text{PRESS} = \sum_{i=1}^n \left(\frac{e_i}{1 - h_{ii}} \right)^2$$

$$R^2_{\text{PRESS}} = 1 - \frac{\text{PRESS}}{SS_{\text{Total}}}$$

Remember to adjust for intercept when finding total sum of squares

c) PRESS:

% To find PRESS
